

9056

5 A client application sends a request to a given server
of a replicated group of servers, and expects a response to
the request. If the client does not receive a response to
the request, or if the server is otherwise unavailable, the
client is automatically reconnected to another server of the
10 replicated group. The servers of the replicated group do
not, however, have to have any knowledge of the
communication session of the client.
